This chapter is your guide to using Photoshop's basic tools. Chapters 3 and discuss more advanced topics, such as color correction and design. Understanding Photoshop's Layered Editing System Photoshop works with a layer-based editing system.

A layer is a rectangular box that's placed on top of other layers. When you open a new document, Photoshop automatically creates a single layer. As you work, you can add layers with your own creations. The layers together form your image. So, with layers, as you work on an image, you alter or create sections of the image without erasing anything else. Layers are sometimes referred to by their layer numbers. Photoshop calls the topmost layer the Background layer, and each layer in descending order is numbered 1 through 10. Note: Not all programs use a numbered hierarchy, but many do. If you're using an earlier version of Photoshop or another program that doesn't use a layer hierarchy, you may need to number your layers yourself. The process is straightforward, and if you need a refresher, check out Book IV, Chapter 6. Understanding Layers You may have to close a layer before you can select it. For example, when you adjust the exposure on a white sky, only the topmost layer is visible. You don't see any of the layer below it. To close a layer, click the small triangle icon in the Layers panel or window, or double-click the layer, and then click OK. You also can use the Select/Deselect tool to move the selected layer to a different layer or to close it. To see the contents of a layer, click the eye icon to toggle between showing and hiding the layer. Be aware of the order in which you move layers. The order should be reversed. For example, when you create a new layer, it should be the first layer in the list, called the topmost layer. To see a list of all the layers, click the Layers panel or window at the bottom of the workspace. If you're already in the panel, click the Eye icon on the panel to toggle between showing and hiding the layers. When you make changes to a layer, always apply those changes to all open layers — not just the topmost one. Otherwise, you may lose the changes you make to the topmost layer when you close a layer. (In fact, you almost always have to.) Using

1. Field of the Invention The present invention relates to valve control devices and a method for assembling these devices. More specifically, the present invention relates to control devices for controlling the flow of fluid from a fluid source to a fluid destination, the control device including a plurality of fluid ports, each of which is adapted to be opened and closed by an actuation member. The invention is especially suitable for fluid control devices that are used in the medical industry, although the invention also is applicable to numerous other uses. 2. Description of the Related Art Many different types of valve control devices are well known in the medical industry, for use in controlling the flow of medical fluids. Many of these devices are assembled by hand or by mechanically-operated automatic assembly methods, such as robots. The following U.S. patents illustrate valve control devices known in the art: U.S. Pat. No. 4,906,996 Ciliberto et al. Mar. 6, 1991; U.S. Pat. No. 5,981,094 Shorrock Sep. 21, 1997; U.S. Pat. No. 5,959,907 Stryker Aug. 25, 1998; U.S. Pat. No. 5,927,019 Shorrock Oct. 9, 1998; U.S. Pat. No. 5,871,734 Ciliberto et al. Feb. 3, 1998; U.S. Pat. No. 5,158,790 Ciliberto et al. Jan. 16, 2000; U.S. Pat. No. 6,557,425 Ciliberto et al. Jul. 22, 2001; U.S. Pat. No. 6,728,632 Ciliberto Aug. 4, 2007. U.S. Pat. No. 4,906,996 (Ciliberto et al.) discloses a valve control device that includes a body defining a first cavity and a second cavity. The body defines a fluid inlet port, a fluid outlet port and a plurality of fluid flow paths connecting the first cavity to the second cavity. Each of the fluid flow paths includes a valve member slideably disposed in the valve body. A thrust surface on the valve member is positionable adjacent to a valve seat defined in the valve body between the second and first cavities to block fluid communication therebetween. A sleeve is disposed within the cavity defined by the valve body. The sleeve is positionable to provide fluid communication through the valve body. An actuation member is disposed on the sleeve and provides for axial movement of the sleeve with respect to the valve body to thus position the thrust surface of each of the valve members with respect to the

What's New In?

A telecommunications system typically includes a plurality of customer service representatives or "agents" who provide customer service over the telecommunications system. For example, a central office telecommunications system could have many area offices which are connected to each other through a regional or toll office. The central office, area office, and regional office comprise a "local loop" that is the loop of wire that connects to a residence or business. Thus, the local loop is the last connection or interface between the telecommunications service provider and the individual who may be accessing the services. The local loop could be the last point of connection before a switch or access device at the customer's residence. In addition to providing telecommunications services, many telecommunications service providers provide maintenance and repair services to the telecommunications system that comprises the local loop. For example, a telephone company may have its own technicians who are employed directly by the telephone company or may contract with a third party to perform the maintenance and repair. During the course of providing service, service providers often need to test or "troubleshoot" the local loop. For example, during a service call, a service provider is often required to identify the type of connection at the customer's premises. In other words, the service provider will typically have to determine whether the connection is an analog telephone line, a digital data line, a cable modem connection, or some other type of connection. For example, in detecting analog telephone line connections, a service provider may need to determine whether the local loop is a twisted-pair connection or an "unshielded twisted pair" connection. A testing arrangement is often used to test the local loop. In particular, a testing arrangement of the type described herein is an apparatus that is generally used to determine the type of connection at a customer's premises, as well as the type of service provided through that connection. This type of testing arrangement is typically mounted outside of the customer's residence. It typically includes a test station or test unit that is physically connected to a port on a jack or connector located near the customer's premises. The connector is connected to the local loop and is secured to a mounting structure that is located remotely from the customer's premises. The test station or test unit is often mounted directly on a mounting bracket that is fixed to the mounting structure. The mounting structure could be mounted to a wall located near the customer's premises, to a pole, or to some other mounting structure. The size of the test station or test unit depends upon the local loops
