Prevention of heterotopic ossification following total hip arthroplasty. Ossification of soft tissue is a well recognized complication after hip arthroplasty. The incidence of heterotopic bone formation increases with age, but it also occurs in younger patients after operations of other joints. Non-operative treatments for established heterotopic bone have not been consistently successful, particularly because bone formation is most likely to occur in the first postoperative month. A carefully selected surgical procedure might obviate these problems, but existing surgical procedures are technically demanding and are not widely practiced. We tried to test the effectiveness of a simple, minimally invasive surgical technique for the prevention of heterotopic ossification. Thirty-one patients who had previously had a total hip arthroplasty were randomized into three groups. Group 1 had 28 patients who had a dorsi-flexing drill hole made at the time of acetabular reaming, and group 2 had 8 patients who had the same surgical procedure without a drill hole. Group 3 had 7 patients in whom acetabular reaming and soft tissue resection alone were performed. One year postoperatively all patients were evaluated radiographically by one observer for the formation of ossification at the surgical site. All patients who had a drill hole showed good results. A moderate incidence of heterotopic bone formation occurred among group 2 patients without a drill hole. Patients in group 3, who had a combination of acetabular reaming and soft tissue resection, had the most excellent results. A simple, minimally invasive surgical procedure effectively inhibits the formation of heterotopic bone. This procedure is not difficult to learn. We recommend that this surgical method be used widely to prevent heterotopic bone formation.

Q: Synchronize terminal outputs I have a terminal output in my input method in my emacs, like in Notepad++. For example, if i press ^D to input exit, this statement is output in my terminal: [-] Elipsis... The important fact is I don't know where this message is output. My question is, is it possible to transfer this output to my input method?? For example, I press ^D to transfer the output to my input method, so if the output is [-] Elipsis..., I want to input this elipsis. A: The output is actually not sent to the terminal. It is written to a hidden buffer called pty-transient-output. You can inspect it if you set a pty mode in your init file, then visit a file to view it in your editor. Here's an example from my init.el: (setq buffer-disable-current-message t buffer-disable-visual-repainting t (goto-char last-input-event-end) pty-mode t) You can inspect this buffer using (pty-view-transient-output), something like this: (find-file "~/foo.txt") (pty-view-transient-output) If you then interact with the pty-transient-output window, you'll see your cursor move to match the text that is being output to your tty. Also, it is not possible to edit this window in a traditional editor (it is just a buffer that Emacs displays in a special mode). It would be very, very inefficient to transfer this output to your input method - it would be quite hard to detect what you are really trying to do, how would it know to stop when you press ^D or ^C etc?
