Q: Could a microbial assemblage of species collectively metabolizing single-carbon compounds support higher life forms? With the arguable exception of single-carbon atoms, most biological organisms known to date must obtain their building blocks from the substrates they metabolize. The surfaces of rocks, for example, are composed of carbon, hydrogen, nitrogen, oxygen and, inorganic minerals such as silica, silicates, and oxide-silicates of iron, magnesium, calcium, potassium, etc. The surfaces of these rocks are thus accessible to microbial living organisms. Single-carbon compounds can have many variations. For instance, single-carbon atoms may be made from carbon-based compounds such as the amino acids: (CH₃CH(OH)CH₃) (glycine) and (CH₃CH₂CH₂CH₂) (valine). They may also be made from cyano-carbon-compounds such as (HCN) (cyanide). Could a microbial assemblage of species (proteins, DNA, enzymes, etc.) collectively metabolizing single-carbon compounds support higher life forms? A: Such an idea was investigated by Baur and Tooms (2013) and Langer et al (2013). The authors considered microbial fixation of molecular hydrogen and carbon monoxide as an alternative to the current chemical fixation in photosynthetic oxygenic photosynthesis. The paper summarizes their study of the ability of anaerobic hydrogenotrophic chemolithoautotrophic acetogenic bacteria to grow on elemental carbon as substrate. It is found that the chemolithoautotrophic acetogens able to grow on carbon-fixation under anaerobic and methane-rich conditions are isolated from the environments containing coal, oil shale and sedimentary rocks. The working hypothesis of the Baur and Tooms (2013) was that the distributions of hydrogenotrophic acetogens and of the other chemolithoautotrophic acetogens are related to the mofeted geochemical conditions favouring these chemolithoautotrophic acetogens. Comparison of the efficacy and efficacy parameters of six high-dose vitamin B6 (pyridoxine hydrochloride) and folate treatments for 10 mg cyanocobalamin every 12, 24, and 48 hours. We compared the treatment of vitamin B6- and folate-deficient subjects with high-dose vitamin B6 or folate and the effects of vitamin B6 and folate on homocysteine metabolism. One hundred seventeen male subjects were divided into six groups: no micronutrient deficiencies, folate deficiency, high-dose vitamin B6 administered every 12 hours, high-dose vitamin B6 administered every 24 hours, high-dose vitamin B6 administered every 48 hours, and high-dose vitamin B6 and folate. The men were fed a controlled diet in which they were B-vitamin replete (1.45 mg of thiamine, 0.6 mg of riboflavin, 0.7 mg of niacin, 0.1 mg of biotin, 55 mg of vitamin B6, and 0.5 mg of folate). The mean plasma homocysteine and pyridoxal 5'-phosphate concentrations were significantly higher in the folate-deficient group than in the normal subjects (22.6 +/- 2.7 mumol/L vs 9.6 +/- 0.9 mumol/L, P
