distractor-present and distractor-absent environments: Effects of working memory capacity, visual
search, and planning ability. Successful plan execution is known to be facilitated by working memory
(WM) capacity. Furthermore, the ability to plan based on a cognitive map, as opposed to an abstract
spatial code, is typically associated with high WM capacity and with good visuospatial skills.

However, little attention has been paid to what cues available in the environment could modulate
performance in the context of WM and planning ability. In the current study, we examined the effect
of visual search and planning ability on the execution of a simple task-based planning task, involving
three levels of WM capacity and modulated by the presence or absence of a distractor object. In one-
step tasks, participants performed an arbitrary movement of a virtual object. Participants were asked
to plan and execute a movement at a later time based on the verbal instruction ("reach") given at
the beginning of the experiment. Performance in the presence of a distracting object was impaired,
but only for participants with a low WM capacity. Interestingly, planning ability was also significantly
influenced by the presence of distractors, with planning ability decreasing as WM capacity increased.

Furthermore, we manipulated the cue used to plan the action in a target-based experimental
condition and found that performance in this condition was modulated by WM capacity, visual search
ability, and planning ability. Our findings underscore the need to consider the environment and its
effect on planning ability and WM capacity when examining plan execution and the potential
influence of WM capacity and planning ability on performance of complex social and/or cognitive
activities. (PsycINFO Database Record (c) 2019 APA, all rights reserved).Q: Prove C# language does
not express all programs. Because of the language is context-sensitive, it does not express all
programs. The number of context-free languages is uncountable, therefore proving that C# does not
express all programs is practically impossible. Question: Please explain the part of above
